Department I - C Plus Plus

Modern and Lucid C++ Advanced for Professional Programmers

Week 5 - Iterators & Tags

Thomas Corbat / Felix Morgner Rapperswil, 16.03.2020 FS2020

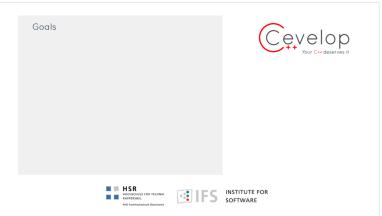

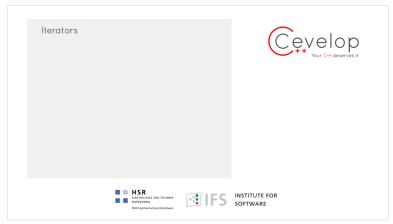

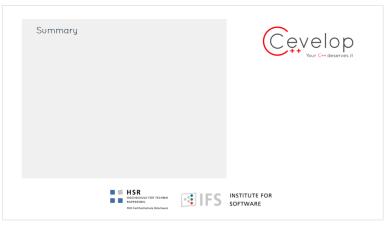

Agenda

Recap Week 4

- Explicit heap memory allocation
 - new expression
- Syntax

```
new <type> <initializer>
```

- Allocates memory for an instance of <type>
- Returns a pointer to the object or array created (on the heap)
 - of type <type> *
- The arguments in the <initializer> are passed to the constructor of <type>

```
struct Point {
  Point(int x, int y) :
       x \{x\}, y \{y\}\{\}
 int const x, y;
};
Point * createPoint(int x, int y) {
  return new Point{x, y}; //constructor
Point * createCorners(int x, int y) {
  return new Point[2]{{0, 0}, {x, y}};
```

- Explicit heap memory deallocation
 - delete expression
- Syntax

```
delete <pointer>
```

- Deallocates the memory (of a single object) pointed to by the <pointer>
- Calls the Destructor of the destroyed type
- delete nullptr is well defined
 - it does nothing
- Deleting the same object twice is Undefined Behavior!

```
struct Point {
 Point(int x, int y) :
       x \{x\}, y \{y\} \{\}
  int const x, y;
void funWithPoint(int x, int y) {
 Point * pp = new Point{x, y};
  //pp member access with pp->
 //pp is the pointer value
  delete pp; //destructor
```

Simple rules

- Delete every object you allocated
- Do not delete an object twice
- Do not access a deleted object

Just don't do the following

```
void foo() {
  int * ip = new int{5};
  //exit without deleting
  //location ip points to
```

```
void foo() {
  int * ip = new int{5};
  delete ip;
  delete ip;
```

```
void foo() {
  int * ip = new int{5};
  delete ip;
  int dead = *ip;
```

Goals

Participants should...

- ... understand the purpose of tag types
- ... be able to explain how tag types can be used to control overload resolution of a function template
- ... be able to implement their own iterator types
- ... be able to facilitate boost to reduce boilerplate code for implementing iterator

Tags for Dispatching

- Template parameters don't require a specified type hierarchy
 - but they expect an argument to satisfy a concept
- Example

```
template <typename Type>
Type max(Type value1, Type value2) {
  return value1 < value2 ? value2 : value1;
}</pre>
```

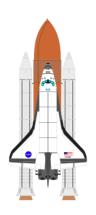

- Operator < must be available to compare Type objects and the result must be convertible to bool</p>
- Type must be move- or copy-constructible
- int or std::string would satisfy the concept of Type

- If the same operation can be implemented more/less efficiently depending on the capabilities of the argument, tags can be used to find the "best" implementation
- Let's have a look at a hypothetical example
 - Different types of space ships have different means of travel (API)

```
template <typename SpaceShip>
void travelTo(Galaxy destination, SpaceShip & ship) {
   ship.$functionUsedToTravel$(destination);
}
```

```
struct MultiPurposeCrewVehicle {
  void travelThroughSpace(Galaxy destination);
};
```

```
struct GalaxyClassShip {
  void travelThroughSpace(Galaxy destination);
  void travelThroughHyperspace(Galaxy destination);
};
```

```
struct HeartOfGold {
  void travelThroughSpace(Galaxy destination);
  Galaxy travelImprobably();
};
```

```
//Provides travelThroughSpace
struct SpaceDriveTag {};

//Provides travelThroughSpace and travelThroughHyperspace
struct HyperspaceDriveTag : SpaceDriveTag {};

//Provides travelThroughSpace and travelImprobably
struct InfniteProbabilityDriveTag : SpaceDriveTag {};
```

- Tag types are used mark capabilities of associated types
- Such tag types do not contain any members
- It is possible to derive tag types from each other to "inherit" the capabilities

 Space ship example: Every space ship can somehow travel through space, but some space ships have more advanced technology

```
struct SpaceDriveTag {};
struct HyperspaceDriveTag : SpaceDriveTag {};
struct InfniteProbabilityDriveTag : SpaceDriveTag {};
```

```
struct MultiPurposeCrewVehicle;
struct GalaxyClassShip;
struct HeartOfGoldPrototype;
```

- Approach 1: Derive space ship from the associated tag type
 - This is not applicable for all types (e.g. for primitive types)
 - This is not extensible (i.e. you cannot specify new kinds of tags as a user of the API)
- Approach 2: SpaceshipTraits template

```
template<typename>
struct SpaceshipTraits {
  using Drive = SpaceDriveTag;
};
```

```
template<>
struct SpaceshipTraits<GalaxyClassShip> {
  using Drive = HyperspaceDriveTag;
};
```

```
template<typename Spaceship>
void travelToDispatched(Galaxy destination, Spaceship & ship, SpaceDriveTag) {
  ship.travelThroughSpace();
template<typename Spaceship>
void travelToDispatched(Galaxy destination, Spaceship & ship, InfniteProbabilityDriveTag) {
 while(destination != ship.travelImprobably());
template<typename Spaceship>
void travelTo(Galaxy destination, Spaceship & ship) {
 typename SpaceShipTraits<SpaceShip>::Drive drive{}; //instance of the spaceship's Drive
 travelToDispatched(destination, ship, drive);
                                                 //call overloaded function
```

- A call of travelTo with a HeartOfGold space ship instance as argument will use the travelImprobably function
- A call of travelTo with any other space ship with the SpaceDriveTag in the SpaceshipTraits template will use travelThroughSpace

Iterators

Different algorithms require different strengths of iterators

- OutputIterator write results, without specifying an end
 - operator * returns an Ivalue reference for assignment of the value
- InputIterator read sequence once
 - operator * returns const Ivalue reference, or rvalue
- ForwardIterator read/write sequence, multiple passes
 - const version: operator * returns const lvalue reference or rvalue
 - non-const: operator * returns lvalue
- BidirectionalIterator read/write sequence, back-forth
- RandomAccessIterator read/write/indexed sequence
- More versatile iterators can be used for more efficient algorithm (like space ships)
- Iterator's capabilities can be determined at compile time (with tag types)

Provide member types

Member	Description
iterator_category	Specifies the iterator category by tag
value_type	Specifies the type of the elements the iterator iterates over
difference_type	Specifies the type used to specify iterator distance (ususally ptrdiff_t)
pointer	Specifies the pointer type for the elements the iterator iterates over
reference	Specifies the reference type for the elements the iterator iterates

• Example:

```
struct IntIterator {
  using iterator_category = std::input_iterator_tag;
  using value_type = int;
  using difference_type = ptrdiff_t;
  using pointer = int *;
  using reference = int &;
};
```

- Implement members required by your ?_iterator_tag
- Example: InputIterator (Concept)

```
struct IntIterator {
 using iterator_category = std::input_iterator_tag;
 using value_type = int;
 using difference_type = ptrdiff_t;
 using pointer = int *;
 using reference = int &;
 //operator *
 //operator ->
  //operator ++ (prefix)
 //operator ++ (postfix)
 //operator ==
  //operator !=
```

Example DIY Iterator for Integers

```
struct IntIterator { /* Member Types Omitted */
  explicit IntIterator(int const start = 0) :
    value { start } {}
  bool operator==(IntIterator const & r) const {
    return value == r.value;
  bool operator!=(IntIterator const & r) const {
    return !(*this == r);
  value_type operator*() const {
    return value;
  IntIterator & operator++() {
    ++value;
    return *this;
  IntIterator operator++(int) {
    auto old = *this;
    ++(*this);
    return old;
private:
 value_type value;
```

Explicit constructor

Implement != through operator ==

Implement postfix through prefix operators

Reuse pre-defined type

```
struct input_iterator_tag{};
struct output_iterator_tag{};
struct forward_iterator_tag : public input_iterator_tag{};
struct bidirectional_iterator_tag : public forward_iterator_tag{};
struct random_access_iterator_tag : public bidirectional_iterator_tag{};
```

- Iterators define type aliases for common usage
- std::iterator<> base class provides defaults (Pre C++17)

```
C++03 Style with typedef
```

```
template<typename InputIterator, typename Tp>
typename iterator_traits<InputIterator>::difference_type
  count(InputIterator first, InputIterator last, const Tp& value) {
    ...
```

- STL algorithms often want to determine the type of some specific thing related to an iterator -> use optimal solution!
- However, not all iterator types are actually classes, i.e., subclasses of std::iterator<>.
- Default iterator_traits just pick the type aliases from those provided by base class std::iterator
- Specialization of iterator_traits also allows "naked pointers" to be used as iterators in algorithms (that is the main reason for the separate traits mechanism)

Simple function overload resolution determines which implementation to use

```
template<typename InputIter, typename Distance>
void advanceImpl(InputIter & i, Distance d, std::input_iterator_tag) {
   while (d--) { i++; }
}

template<typename RandomAccessIter, typename Distance>
void advanceImpl(RandomAccessIter & i, Distance d, std::random_access_iterator_tag) {
   i += d;
}

template<typename InputIter, typename Distance>
void advance(InputIter & i, Distance n) {
   typename std::iterator_traits<InputIter>::difference_type d = n;
   advanceImpl(i, d, typename std::iterator_traits<InputIter>::iterator_category{});
}
```

::advance(iter, 15);

```
#include <boost/iterator/counting_iterator.hpp>
#include <boost/iterator/filter_iterator.hpp>
#include <boost/iterator/transform_iterator.hpp>
```

- Several pre-defined adapters with factory functions, for example
 - Counting
 - Filtering
 - Transforming
- See also
 - http://www.boost.org/doc/libs/1_72_0/libs/iterator/doc/index.html

```
struct odd {
  bool operator()(int n) const {
    return n % 2;
int main() {
  using counter = boost::counting iterator<int>;
  std::vector<int> v(counter{ 1 }, counter{ 11 });
  std::ostream iterator<int> out { std::cout, ", " };
  copy(v.begin(), v.end(), out);
  std::cout << '\n';</pre>
  copy(boost:: make_filter_iterator(odd{}, v.begin(), v.end()),
       boost::make_filter_iterator(odd{}, v.end(), v.end()), out);
  std::cout << '\n';</pre>
  auto sq = [](auto i) {return i * i;};
  copy(boost::make_transform_iterator(v.begin(), sq),
       boost::make transform iterator(v.end(), sq), out);
```

Functor for filtering

Counting iterator

Filter iterator only odd values provided

transform iterator applies function/functor/lambda for each value

Inherit and provide own iterator

- Class as first template argument
- Second argument for value_type
- Other template arguments are usually defaulted and OK
- input_iterator_helper<T, V>
- forward_iterator_helper<T, V>
- bidirectional_iterator_helper<T, V>
- random_access_iterator_helper<T, V>
- output_iterator_helper<T>
 - Output only is special, no value type, special requirements!

Using boost/operators.hpp shortens definition

Pass own type
CRTP = Curiously Recurring Template Parameter

```
struct IntIteratorBoost
                 : boost::input iterator helper<IntIteratorBoost, int> {
                 explicit IntIteratorBoost(int start = 0)
  Explicit
                   : value { start } {}
Constructor
                 bool operator==(IntIteratorBoost const & r) const {
                   return value == r.value;
                 value type operator*() const { return value; }
  Reuse
                 IntIteratorBoost & operator ++() {
predefined
                   ++value;
   type
                   return *this;
               private:
                 value type value;
               };
```

Inherit to obtain types and operations (through CRTP)

operator== required

- Rarely needed, special tricks required
- operator* just returns this, operator++ is a no-op
- operator= defines output of value
- *out++ = 42; // works

```
struct MyIntOutIter {
  using iterator_category = std::output_iterator_tag;
 using value type = int;
  /* Other Member Types Omitted */
 MyIntOutIter & operator++() {
   return *this;
 MyIntOutIter operator++(int) {
   return *this;
 MyIntOutIter const & operator*() const {
   return *this;
 void operator=(value type val) const {
   std::cout << "val = " << val << '\n';
```

- Even simpler with Boost
- operator= defines output of value
- *out++ = 42; // works

```
struct MyIntOutIterBoost : boost::output_iterator_helper<MyIntOutIterBoost> {
  void operator=(int val) const {
   std::cout << "value = " << val << '\n';
  }
};</pre>
```

An output iterator for summing and averaging

```
struct SummingIter {
 using iterator_category = std::output_iterator_tag;
 using value type = int;
 /* Other Member Types Omitted */
 void operator++() { ++counter; }
 SummingIter & operator*() {
    return *this;
 void operator=(int val) {
    sum += val;
 double average() const {
    return sum / coutner;
 double sum{};
  size_t counter{};
```

```
std::vector<int> v {3, 1, 4, 1, 5, 9, 2};
auto res = copy(v.begin(), v.end(), SummingIter{});
std::cout << res.sum << " average: "<< res.average();</pre>
```

```
IntInputter();
value_type operator*();
bool operator==(IntInputter const & other) const;
```

- How do we initialize the reference in the default constructor?
- What should happen in operator*()?
- How can we compare iterators to guarantee equality for EOF-condition?

```
IntInputter();
```

- We need a dirty trick: A global variable to initialize the reference!
 - Put it into an anonymous namespace to hide it
 - Not good for multi-threading -> bad for production code

```
namespace {
    // a global helper needed...
    std::istringstream empty{};
}
IntInputter::IntInputter()
    : input { empty } {
    // guarantee the empty stream is not good()
    input.clear(std::ios_base::eofbit);
}
```

```
value_type operator*();
bool operator==(IntInputter const & other) const;
```

Just input

```
IntInputter::value_type IntInputter::operator*() {
  value_type value{};
  input >> value;
  return value;
}
```

- And Compare. Only equal if both are !good()
 - Both eof() would result in problems on failing input when using standard algorithms

```
bool IntInputter::operator==(const IntInputter & other) const {
   return !input.good() && !other.input.good();
}
```

```
struct IntInputter {
  using iterator category = std::input iterator tag;
 using value_type = int;
  /* Other Member Types Omitted */
  IntInputter(); ——
                                                                        Default Constructor
  explicit IntInputter(std::istream & in)
                                                                              for EOF
    : input { in } {}
 value type operator*();
  IntInputter & operator++() {
                                                                          ++ does nothing
    return *this;
  IntInputter operator++(int) {
   IntInputter old{*this};
   ++(*this);
   return old;
                                                                         Equal only if both
  bool operator==(IntInputter const & other) const; 
                                                                                EOF
  bool operator!=(IntInputter const & other) const {
   return !(*this == other);
                                                                         Caller must guarantee survival
                                                                         of object, otherwise "dangling"
private:
  std::istream & input; ——
                                                                                   reference!
```

- Alternative to global variable: Naked pointer that might point to "nothing"
 - A pointer can be empty, which requires a check
- Boost can be used for brevity

```
value_type operator*();
bool operator==(IntInputter const & other) const;
```

Input only if defined

```
IntInputterPtrBoost::value_type IntInputterPtrBoost::operator*() {
   value_type value{};
   if (input) (*input) >> value;
   return value;
}
```

And Compare. Only equal if both are either nullptr or !good()

```
bool IntInputterPtrBoost::operator==(IntInputterPtrBoost const & other) const {
   return (!input || !input->good()) && (!other.input || !other.input->good());
}
```

Summary

- Tag types can be used for static dispatching (For example in iterators)
- DIY Iterators are used much less often than functors for parameterizing the standard library algorithm
 - Try one of the boost adapters first
- They need pre-defined member types to work with the standard algorithms
 - as well as a set of operators
 - if DIY <boost/operators.hpp> provides boilerplate code
